## Use Case Prioritization - Student Portfolio Case Study

NovaTech Industries GmbH is a fictional company. All use cases, values, costs, risks and timelines in this document are synthetic.

|--------------------|------------------|--------------------|-----------------|
| 24<br>AI use cases | 8<br>departments | 8<br>high priority | 8<br>quick wins |
|--------------------|------------------|--------------------|-----------------|

### Project objective

The project explores how a business analyst might move from a long list of AI ideas to a smaller, explainable set of pilot priorities. The scoring model balances value with feasibility, data readiness, effort, risk and basic ROI attractiveness.

### Enterprise AI Transformation - Executive Overview

NovaTech Industries GmbH | fictional student case study | synthetic data

# How the opportunities were prioritized

Each use case is rated from 1 to 5 on business value, feasibility, data readiness, implementation effort and risk. Ease of implementation and risk advantage are calculated as the inverse of effort and risk. A simple annual-value / implementation-cost ratio is converted to a 1-5 ROI score.

| Dimension              | Weight | Reason                                                 |
|------------------------|--------|--------------------------------------------------------|
| Business Value         | 30%    | Keeps business impact as the strongest driver          |
| Feasibility            | 20%    | Avoids prioritizing ideas that are too hard to execute |
| Data Readiness         | 15%    | Reflects whether the idea has usable input data        |
| Ease of Implementation | 15%    | Rewards simpler first pilots                           |
| Risk Advantage         | 10%    | Rewards ideas with more manageable risk                |
| ROI Attractiveness     | 10%    | Adds a basic value-versus-cost check                   |

Bubble size reflects priority score. Labels show the high-priority cases plus selected strategic items; overlapping labels are offset for readability.

# Roadmap and process transformation

The portfolio is phased so the company can learn from manageable pilots before moving to use cases with heavier integration, model monitoring or operational dependencies.

Roadmap is intentionally staged: build experience with simpler workflow use cases before the most integration-heavy opportunities.

Invoice processing is used as the process example. The future state automates extraction and basic matching, but keeps human approval for exceptions and financial controls.

## Invoice Processing - Current State vs Proposed Future State

AI supports repetitive work; human control stays for exceptions

## Risk, governance and student takeaway

The case study does not treat AI adoption as only a technology question. A small risk register captures privacy, incorrect output, bias, information security, source-data quality, adoption, integration and vendor dependency.

The register focuses on practical project risks: privacy, incorrect output, bias, security, data quality, adoption, integration and vendor dependency.

## Student takeaway

The most important lesson for me was that the highest-value use case is not automatically the right first pilot. A useful first project also needs a clear owner, usable data, manageable risk, realistic integration effort and a measurable success criterion.

This document is part of an independent educational portfolio project. It does not represent work completed for a real client or employer.
